Manuscript Number:

Dear Iphan F. Radam,

Mr. Hendri Yani Saputra submitted this manuscript via Elsevier's online submission system, Editorial Manager, and you have been listed as a Co-Author of this submission. Elsevier asks Co-Authors to confirm their consent to be listed as Co-Author and track the papers status. In order to confirm your connection to this submission, please click here to confirm your co-authorship:

<https://www.editorialmanager.com/ijstst/l.asp?i=57021&l=0V6WGTW2>

If you have not yet registered for the journal on Editorial Manager, you will need to create an account to complete this confirmation. Once your account is set up and you have confirmed your status as Co-Author of the submission, you will be able to view and track the status of the submission as it goes through the editorial process by logging in at

<https://www.editorialmanager.com/ijstst/>

If you did not co-author this submission, please contact the Corresponding Author directly at 1920828310054@mhs.ulm.ac.id

Thank you,

International Journal of Transportation Science and Technology

Accessibility model of BRT stop locations using Geographically Weighted Regression (GWR): A case study in Banjarmasin, Indonesia

--Manuscript Draft--

Manuscript Number:	IJTST-D-22-00025R2
Article Type:	Research Paper
Keywords:	BRT; GWR; Accessibility model; Transit accessibility; System accessibility
Corresponding Author:	Hendri Yani Saputra Lambung Mangkurat University: Universitas Lambung Mangkurat INDONESIA
First Author:	Hendri Yani Saputra
Order of Authors:	Hendri Yani Saputra Iphan F. Radam, Professor
Abstract:	<p>Bus Rapid Transit (BRT) has advantages over rail-based systems as a public transportation system. The ease of implementation and low investment costs attract many cities to develop BRT systems, including Banjarmasin, Indonesia. Banjarmasin currently has eight BRT stop points that reach only two sub-districts out of five. The limited range of BRT stops within the city can affect the level of accessibility of the BRT system. The accessibility of the transit system itself can be seen from the number of daily passengers. This study aims to analyze the criteria that affect the level of accessibility of the BRT stops in the study area and then compile a model based on significant criteria. Previous literature on accessibility modeling shows varied methods and approaches. In this study, the system accessibility was measured using the composite method and modeled using Geographically Weighted Regression (GWR), which is a relatively new approach. The results show that seven criteria affect the level of accessibility of the BRT stops. The model was first built mathematically using OLS. Then, GWR analysis was accomplished on spatial variables, resulting in a higher significance model. Furthermore, the GWR produces a visual-spatial model and performs simulation and sensitivity tests to make the research purpose more informative. The spatial criteria for the accessibility of the BRT stop locations in the model include the distance of stops to the road intersection, mix-use entropy index, population density, and land value.</p>

1. Review:

Introduction: Two Research Questions are listed. Please list out the objectives of the study explicitly.

Response:

Thank you for pointing this out. We agree that the introduction has not explicitly stated the research objectives. Therefore we add it (Ln. 98 Page 3). Furthermore, we explain the paper's outline at the end of the introduction paragraph (Ln. 100 Page 3).

2. Review:

GWR is mentioned for the first time in the manuscript (other than Abstract). Please spell the full form.

Response:

Thank you for pointing this out. We agree that we missed it. Therefore we spell the full form for the first time in the introduction (Ln. 104 Page 4).

3. Review:

The authors need to check the manuscript properly. There are grammatical errors. Please caption the alphabet "F" for all the figures caption reference, i.e. refer to Figure 2, not figure 2.

Response:

Thank you for pointing this out. We agree that we missed it. Therefore we replace it all and check carefully for other errors.

4. Review:

Re-organize Chapter 3. Explain the research methodology according to Figure 2. Please do not include Literature Review in the methodology. Just focus on the description/explanation on how the methodology is carried out.

Response:

Thank you for pointing this out. We agree that the methodology has several references, including references to the formula we are using for analysis. Therefore we re-organize it to Chapter 2 and focus Chapter 3 on methodology according to Figure 2.

Reviewer #2

Review:

The authors have largely written the manuscript to respond to the comments raised in the previous round. Few more issues to be further addressed; then the paper can be considered for publication at IJTST. (The authors can simply make modifications and no need for another round of review).

Response:

Thank you for your appreciation and suggestion. We will try our best to fix the following issues.

1. Review:

Waiting time and O-D data were obtained from the questionnaire survey by directly interviewing passengers onboard, which are supposed to vary across individuals. However, the dependent variable (Y) is the total number of passengers boarding and alighting at each stop. In such a context, how are the disaggregate data (from the questionnaire survey) and aggregate data (at the stop level) related? For example, for waiting time (X1), is the average value (over all boarding passengers) used for each stop?

Response:

Thank you for pointing this out. We agree that we forgot to explain the condition of that related questionnaire (disaggregate data) and on-board survey (aggregate data). In conducting on-board survey, we also interviewed all passengers on the bus, passengers boarding, and passengers alighting, and ensured that no one was missed (not a random sampling questionnaire) as we described in the revised methodology (Ln. 363 Page 10). This method is possible because we realize that the number of

passengers is relatively small and the headway of the bus is very long (> 2 hours) so that when the bus arrives, all the passengers at the stop will get on the bus (the stop has become empty). Thus, the total number of respondents to our questionnaire is the same as the total number of passengers on the day we conducted the on-board survey, which was 137 people.

2. Review:

In the added discussion about mix-used entropy, the authors claim that "the positive sign described its influence direction is linear as if we increased the X4 value, it will increase the accessibility and vice versa." Is it certain that the effect from Y back to X4 also holds?

Response:

Thank you for pointing this out. We were negligent in writing the discussion and forgot that the regression does not work that way. In this paper, we do not observe the influence of the independent variable (Y) on the dependent variable (X). So we do not know the certain effect from Y to the X4, and we should not explain it (by vice versa). Therefore we revised it (Ln. 497 Page 14).

3. Review:

"Data" is a plural noun, while the authors mis-used it as a singular noun at several locations, for example, Ln. 295, Page 8 and Ln. 341, Page 9.

Response:

Thank you for pointing this out. We agree that we mis-used "Data" in singular nouns at several locations. Therefore we revised it.

Kind regards,
Hendri Yani Saputra

14/02/2022

Dear Editorial Board,

We wish to submit an original research article entitled “Accessibility model of BRT stop locations using Geographically Weighted Regression (GWR): A case study in Banjarmasin, Indonesia” for consideration by the International Journal of Transportation Science and Technology. We confirm that this work is original and has not been published elsewhere, nor is it currently under consideration for publication elsewhere.

In this paper, we try to model the accessibility level of Bus Rapid Transit (BRT) stops as a public transportation system. This modeling specifically involves spatial criteria and is analyzed using Geographically Weighted Regression (GWR) where this is a new approach method in accessibility modeling, especially in system accessibility. Finally, modeling with this method can show more significant and informative results that might help cities develop more effective BRT systems.

We believe that this manuscript is appropriate for publication by the International Journal of Transportation Science And Technology because it concerns the study of transportation science that your journal is interested in.

We have no conflicts of interest to disclose.

Please address all correspondence concerning this manuscript to me at (1920828310054@mhs.ulm.ac.id).

Thank you for your consideration of this manuscript.

Sincerely,

Hendri Yani Saputra

Response to Reviewers

Title: Accessibility model of BRT stop locations using Geographically Weighted Regression (GWR): A case study in Banjarmasin, Indonesia

Manuscript number: IJTST-D-22-00025R1

Revision Version: 2

Editor's Decision Received Date: May 22, 2022

Revision Submission Date: Jun 12, 2022

Dear Dr. Ruey (Kelvin) Cheu

Thank you for giving us another opportunity to submit a revised draft of our manuscript titled "Accessibility model of BRT stop locations using Geographically Weighted Regression (GWR): A case study in Banjarmasin, Indonesia" to the International Journal of Transportation Science and Technology. We appreciate the time and effort that you and the reviewers have dedicated to providing your valuable feedback on my manuscript. We have been able to incorporate changes to reflect most of the suggestions provided by the reviewers.

Here is a point-by-point response to the reviewers' comments and concerns.

Reviewer #1

1. Review:

28 **Abstract**

29

30 Bus Rapid Transit (BRT) has advantages over rail-based systems as a public transportation system.
31 The ease of implementation and low investment costs attract many cities to develop BRT systems,
32 including Banjarmasin, Indonesia. Banjarmasin currently has eight BRT stop points that reach only
33 two sub-districts out of five. The limited range of BRT stops within the city can affect the level of
34 accessibility of the BRT system. The accessibility of the transit system itself can be seen from the
35 number of daily passengers. This study aims to analyze the criteria that affect the level of
36 accessibility of the BRT stops in the study area and then compile a model based on significant
37 criteria. Previous literature on accessibility modeling shows varied methods and approaches. In
38 this study, the system accessibility was measured using the composite method and modeled using
39 Geographically Weighted Regression (GWR), which is a relatively new approach. The results
40 show that seven criteria affect the level of accessibility of the BRT stops. The model was first built
41 mathematically using OLS. Then, GWR analysis was accomplished on spatial variables, resulting
42 in a higher significance model. Furthermore, the GWR produces a visual-spatial model and
43 performs simulation and sensitivity tests to make the research purpose more informative. The
44 spatial criteria for the accessibility of the BRT stop locations in the model include the distance of
45 stops to the road intersection, mix-use entropy index, population density, and land value.

46

47 **Keywords:** BRT; GWR; Accessibility model; Transit accessibility; System accessibility

48

49 **Highlights**

50

- 51 • Composite measurement of accessibility can perform more effectively with GWR.
- 52 • GWR performance on spatial variables results in a higher significance model.
- 53 • The Mix-used entropy index criteria have the most significant influence on BRT accessibility.
- 54 • Network Dataset can overcome the high demand for data on accessibility modeling.
- 55 • GWR Simulation produces a visual-spatial model that easy-to-understand.

1. Introduction

Accessibility plays an essential role in a public transportation system. There is awareness of big cities facing the problem of limited provision of transportation infrastructure. However, the demand growth for transportation is continuously increasing to infinity. Hence, cities were challenged to develop public transportation systems with high accessibility, including Mass Rapid Transit (MRT), Light Rail Transit (LRT), and Bus Rapid Transit. (BRT). BRT has advantages in faster implementation, lower costs, and greater strategic effect than rail-based systems (ITDP-Indonesia, 2018).

The existence of public transportation in Banjarmasin such as the minibus taxi or "angkot" experienced a drastic decline both in terms of the number of passengers and fleet. Angkot in its operational service does not have a fixed stop. Their system is confusing because we can get on and get off whenever or wherever we want. To get in the angkot, we just need to stand at the roadside and wave our hands to the driver. Furthermore, private transportation has increased by 10 % yearly and is not proportional to road capacity growth. Existing public transportation only has a percentage of 3.12 % of the total traffic movement in Banjarmasin. One of the causes of this condition is that the existing public transportation conditions are uncomfortable and unattractive (Radam, 2018).

The ineffectiveness of the previous system has led to the Government's initiation to develop a BRT system with an advantage in lower cost and faster implementation. The Banjarbakula BRT system is planned to serve at a metropolitan scale across two cities and three districts. The operation of Banjarbakula BRT in Banjarmasin area currently serves Banjarmasin-Banjarbaru round trips with eight BRT stops within Banjarmasin. In terms of spatial distribution, the locations of BRT stops in Banjarmasin are only in the districts of East Banjarmasin and Central Banjarmasin. The BRT stops are not reached the activity centers in the northern, western, and southern parts of Banjarmasin.

Recognizing the BRT limitation, The Trans-Banjarmasin feeder under different management initiated to connect areas that the Banjarbakula BRT had not reached. However, this feeder uses the existing stop points belonging to the angkot. The problem is that the stop points belonging to angkot are already abandoned because users can get on and off whenever or wherever they want. There is a question about the accessibility of the angkot stop point that is not yet known, and no further study to integrate it into the BRT system.

For reference, the TransJakarta BRT system allows feeder buses to pick up passengers without stopping at designated stops and has many flexible routes. However, the area of activity centers is still supported by the trunk system of TransJakarta (Fitriati, 2010). In the case of TransMilenio Bogota, one of the accessibility criteria is travel time by walking to stops affects the quality of the BRT system, which can increase the value of an area in urban (Munoz-Raskin, 2010).

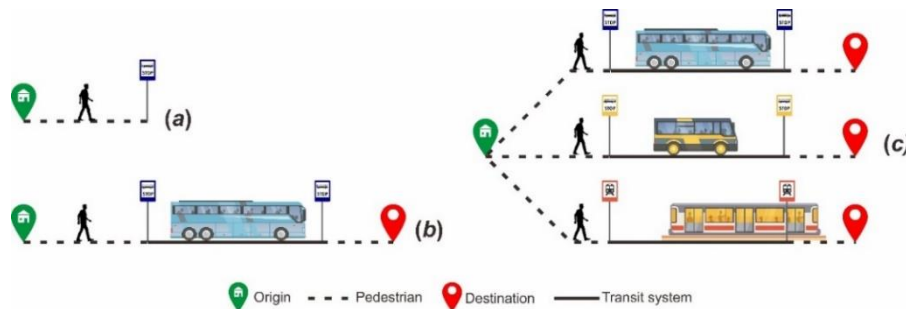

Based on the background above, the main problem is that the development of BRT systems in the study area has not yet considered accessibility a critical factor in the transit system. The re-use stop location of previous public transportation that in fact failed to attract users needs evaluation and further study of its accessibility. Two research questions can be formulated. First, what are the criteria that affected the accessibility of the BRT stop locations. Second, where is the BRT stop's location that meets the criteria of accessibility to develop in the study area. The research objectives are to know the criteria that affect the accessibility of the BRT stop location and develop models and simulations of BRT stop locations with high accessibility criteria in the study area. In the first section, the background and objectives of the research will be explained. The second

102 section contains related literature references, and the third section will explain the methodology
 103 used. The fourth section describes the results and discussion, which closes with the conclusion in
 104 the fifth section. Furthermore, Geographically Weighted Regression (GWR) was expected to
 105 produce a more significant and informative model to answer the research questions.

106
 107 **2. Literature Review**

108
 109 **2.1. The Measurement of Transit Accessibility**

110
 111 In public transportation, there is a definition of accessibility which includes the choice of
 112 modes. Transit accessibility is an accessibility approach that is more specific in measuring the
 113 level of accessibility of the urban transportation system, especially the public transportation system
 114 to the pedestrian system. Transit accessibility emphasizes the point of view of service users (transit
 115 users) in utilizing the existing transit system. These users generally have their own considerations
 116 of accessibility parameters that they think are in accordance with their wishes, such as travel time,
 117 number of transfers, costs/fares, etc. Transit accessibility modeling can be divided into system
 118 accessibility, system-facilitated accessibility, and integral accessibility (Malekzadeh and Chung,
 119 2019). The illustrations can be seen in Figure 1.

121
 122
 123 Fig. 1. (a) system accessibility, (b) system-facilitated accessibility, (c) integral accessibility

124
 125 Systems accessibility deals with physical access to the public transit network, estimating
 126 how easy it is for a person to reach public transit stops using different travel modes or first-mile.
 127 Systems-facilitated accessibility measures a traveler's ability to reach an opportunity by
 128 incorporating the travel time or cost spent in the transit network. Integral accessibility is associated
 129 with measuring overall access to a number of possible destinations, revealing how easy it is for
 130 the resident to travel from an origin to opportunities using public transit (Lei and Church, 2010)
 131 and (Mavoa et al., 2012) as cited in (Malekzadeh and Chung, 2019). In this study, as the BRT
 132 system is in an earlier stage, the output model is optimized for planning the system accessibility.
 133 In planning a public transportation system, access to the transit system is one of the main factors
 134 as important as the quality of the transit system (Mavoa et al., 2012).

135 There are challenges in developing transit accessibility models, and a review of previous
 136 studies from (Malekzadeh and Chung, 2019) shows varied methods and approaches. In terms of
 137 measurement of system accessibility, there are distance-based, gravity-based, and utility-based
 138 models (Malekzadeh and Chung, 2019). The distance-based model is the simplest method in transit
 139 accessibility as it simply incorporates the distance from a given origin to different opportunities
 140 into the model. Some studies have proposed simple straight-line (Euclidean) distances, while

141 others have proposed complicated impedance formulations for weighting the distance to
142 opportunities (Geurs and van Wee, 2004) and (Makrí and Folkesson, 1999), as cited in
143 (Malekzadeh and Chung, 2019). The gravity-based models propose a weight to opportunities
144 representing their attraction and apply an impedance value (decay function) to reflect their distance
145 from the origin (El-Geneidy and Levinson, 2006). The utility-based models are defined based on
146 the "logsum" expression of a random utility model, in which the probability of an individual
147 making a particular choice is related to the utility of all available choices (Ben-Akiva et al., 1985)
148 as cited in (Malekzadeh and Chung, 2019). However, the model with distance-based measurement
149 can not capture the subjectivity in travel behavior. The gravity-based has some points of weakness
150 that are similar to the distance-based. These models have difficulty calibrating their decay
151 functions to capture traveler behavior for accessing transit services (Malekzadeh and Chung, 2019).

152 The utility-based is incorporated individual traveler preferences as part of the accessibility
153 measure. This measure imitates human choice since the attractiveness of each destination is
154 included. It is based on the economic benefits that people derive from accessing certain activities.
155 This measure has several advantages, yet its complexity and data intensity are the main barriers to
156 implementing it (El-Geneidy and Levinson, 2006). Therefore, applying utility models which
157 consider all the benefits that travelers can gain from the choice of destination or land-use supply
158 can provide a more accurate estimation of transit accessibility from the transit user's perspective
159 (Malekzadeh and Chung, 2019). The BRT system in the study area is at an earlier stage and only
160 has eight stop locations, we doubt the distance-based or gravity-based model is enough to simulate
161 further development. Instead, we noticed the advantage of the utility-based model that can help
162 explain the "subjective choice" of the users on their first transit system. It is supported by the fact
163 that the previous public transportation angkot has been abandoned because conditions are
164 uncomfortable and unattractive, although angkot has an advantage in terms of flexibility of stop
165 locations.

166 Composite Accessibility Measure (Miller, 1999) as cited in (El-Geneidy and Levinson,
167 2006) is the combined distance-based and utility-based measures in one measure. However, this
168 approach introduces a higher level of complexity where time constraints are superimposed and
169 requires more data that utility-based and accordingly generalizing it for usage is not an easy task.
170 To get the advantage both of an objective view of distance-based and a subjective view of utility-
171 based measure, we realize the composite measurement is the most suitable in the study area. To
172 help the complexity measurement of composite models, we found that GWR is suitable for dealing
173 with the complex correlation of accessibility criteria on spatial-based data.

174 The shortcomings in measuring accessibility are indications of influential criteria that can
175 cover all aspects of spatial to urban socio-economic, which require quite a lot of data and high
176 computing in the modeling (Liu and Zhu, 2004). To overcome this combined data collection
177 method is used. First, an on-board survey was conducted to get detailed field data. The survey
178 begins with a surveyor boarding a BRT at the origin. While the BRT is traversing its route, the
179 surveyor records the time of movement. The surveyor also records the number of passengers
180 boarding or alighting the BRT at certain points along the route. Therefore, it would comprise the
181 time the BRT moved or stopped and the number of passengers who boarded and alighted the
182 vehicle at a point along the route. The survey terminates once the BRT reaches its end destination
183 (Abad and Fillone, 2014).

184 Field data are verified and combined using crowdsourced data such as Openstreetmap
185 (OSM). The use of crowdsourcing data in the field of transportation engineering could help with
186 complex modeling that requires temporal and spatial data (Kumarage, 2018). Several studies have

187 found that, compared to data from sources such as NMAs, OSM has attained a very high and
188 mature level of completeness and spatial accuracy for various regions of the world (Dorn et al.,
189 2015) as cited in (Antoniou, 2017).

190 Data collection results are managed in the form of the Road Network Dataset or Network
191 Dataset. A network dataset is an abstract representation of the components and characteristics of
192 transportation networks in the real world. One of the technological developments in modeling
193 objects spatially is the GIS which has a spatial analysis approach to transportation networks called
194 network analysis. In carrying out the network analysis, data in the form of an accurate road network
195 dataset is needed (Sadeghi-Niaraki et al., 2011). ArcGIS is one of several software tools that can
196 build, analyze and manage network datasets through network analysis tools. There are several
197 preparing protocols to convert OSM data into ArcGIS Network Dataset. We can not import OSM
198 data directly into ArcMap or convert OSM format (.osm) to ESRI Shapefile (.shp). Importing OSM
199 data directly into a network dataset without preparation can reduce the data quality. This
200 conversion process results in data loss, which leads to an incorrect representation of road networks,
201 particularly at intersections (Masoud and Idris, 2018).

202 Several previous studies attempted to construct a system accessibility model. (Malekzadeh
203 and Chung, 2019) conducted a review of research on modeling the accessibility of modern public
204 transportation, including BRT. Several models of accessibility of transit systems, such as Public
205 Transport Accessibility Level (PTAL) by (Hammersmith and Fulham, 1992), Ideal Stop
206 Accessibility Index (ISAI) and Actual Stop Accessibility Index (ASAI), Stop Coverage Ratio
207 Index (SCRI) by (Foda and Osman, 2010, 2008) for example, has the same objective to capture
208 system accessibility using a distance measurement. Another different approach in system
209 accessibility modeling using utility-based measurement is the Environmental Transit Accessibility
210 Index (ETAI) developed by (Rastogi and Krishna Rao, 2003) and (Rastogi and Rao, 2002), which
211 is based on the subjective choice of stops by passengers. However, most previous studies in system
212 accessibility modeling attempt to evaluate the existing system already developed in their study
213 area. This study had a different purpose as the model was obtained for planning a new optimized
214 system. Besides, GWR had an advantage in the enormous scope of criteria measurement in
215 composite method, visual-spatial model output, and simulation, which is a relatively new approach.
216

217 ***2.2. Geographically Weighted Regression (GWR) in transportation-related studies***

218

219 GWR was the development of a regression model in which each parameter was calculated
220 at each location point, so each geographic location point had a different regression parameter value.
221 The GWR model was a development of the global regression model where the basic idea was taken
222 from non-parametric regression (Mei et al., 2006). The GWR mathematical model can be seen in
223 Equation (1).
224

$$225 \quad y_i = \beta_0(u_i, v_i) + \sum_{k=1}^p \beta_k(u_i, v_i)x_{ik} + \varepsilon_i \quad (1)$$

226
227 Where (u_i, v_i) are the coordinates of the i point and $\beta_k(u_i, v_i)$ is the result of the continuous
228 function $\beta_k(u_i, v_i)x_{ik}$ at the point i , making a surface of the parameter estimates showing any spatial
229 variability. GWR can perform using a fixed and adaptive kernel approach and bandwidth
230 optimization using Cross-Validation (CV) and Akaike Information Criterion Corrected (AICc)

231 methods. The output significance values can compare to finding optimum models (da Silva and
 232 Mendes, 2018).

233 Before performing the GWR regression analysis, a global regression model must be built first.
 234 According to ESRI (<https://desktop.arcgis.com>), a simple Ordinary Least Square (OLS) is
 235 recommended to be built first. Previous research using GWR (Zhou et al., 2019) performed OLS
 236 to remove any outliers and compared their significance. The significant model for OLS can be
 237 determined using several methods. One of them is using best subset regression by comparing
 238 adjusted R^2 and Cp-Mallows values. Mallows proposed the Cp-Mallows criterion in 1972, where
 239 Cp minimum statistics are considered the best model (Hocking and Leslie, 1967). Another
 240 reference is that the best model based on Cp was the model with the closest Cp value to the number
 241 of variables in the model (Hanum, 2011). The Cp-Mallows value was calculated by Equation (2).
 242

$$243 \quad Cp = \frac{RSS_p}{\hat{\alpha}^2} - (n - 2p) \quad (2)$$

244
 245 Where p is the number of variables in the regression, RSS is the residual sum of squares for
 246 the particular p -variate regression being considered, and $\hat{\alpha}^2$ is an estimate of α^2 , frequently the
 247 residual mean square from the complete regression. Moreover, the spatial autocorrelation (Global
 248 Moran's I) for each spatial criteria needs to check to see a spatial dependency using Equation (3).
 249

$$250 \quad I = \frac{n}{S_0} \frac{\sum_{i=1}^n \sum_{j=1}^n w_{i,j} z_i z_j}{\sum_{i=1}^n z_i^2} \quad (3)$$

251
 252 Where z_i is the deviation of an attribute for feature i from its mean ($x_i - \bar{x}$), $w_{i,j}$ is the spatial
 253 weight between feature i and j , n is equal to the total number of features, and S_0 is the aggregate
 254 of all the spatial weights. Several previous studies applied GWR in transportation-related studies,
 255 specifically in the accessibility of the BRT-related system. For reference, (Yang et al., 2020)
 256 researched accessibility and proximity effects of the BRT corridor on housing prices in Xiamen
 257 Island, China, resulting in BRT accessibility premiums and proximity penalties simultaneously
 258 exist in the housing market, and the BRT effect on housing prices is spatially heterogeneous.
 259 Furthermore, the output of GWR has more significant results than global regression. A similar
 260 approach on hedonic price models (Zhang et al., 2020) investigated the connection between the
 261 accessibility of the open-system BRT network and property values in Brisbane, Australia. Using
 262 an improved model of GWR called the Geographically Weighted Generalized Linear model
 263 (GWGLM) that specifically justifies the calibration for individual variables. However, although
 264 using a similar method and objective, the purpose of their study is different as it finds the
 265 connectivity of BRT accessibility and land/property value or hedonic price models.
 266

267 **2.3. The Accessibility Criteria of BRT Stop locations**

268
 269 The accessibility criteria of BRT stop locations or system accessibility can extend from the
 270 measurement method. In this study, the composite measurement method is used. Thus, the criteria
 271 with an objective view from distance-based measurement and a subjective view from utility-based
 272 measurement can be involved. In the distance-based system accessibility modeling, several factors

273 influence the location of the bus stop, including the travel time by walking to the bus stop (Foda
274 and Osman, 2010, 2008), waiting time at the bus stop, and population density around the bus (Zhao
275 et al., 2003), (Polzin et al., 2002) as cited in (Malekzadeh and Chung, 2019). In the urban scale
276 and using a GIS environment (Stewart, 2014) identify these factors of accessibility, such as travel
277 time, reliability, availability of mode interconnection, and cost.

278 Accessibility of BRT is generally defined physically and can be measured globally as a
279 person's travel time from origin to destination using the BRT system. Accessibility criteria
280 themselves globally can include costs or fees, passenger comfort, security, convenience, etc.
281 However, physical accessibility criteria are essential, although they do not describe globally. The
282 criteria for physical accessibility are walking time, which is measured by calculating the walking
283 speed assumption of 4.39 km/h (National Research Council (U.S.). Transportation Research
284 Board., 2000) as cited in (Rodriguez and Targa, 2004).

285 Institute for Transportation and Development Policy (ITDP) published on The BRT
286 Standard 2016 indicates the exact location of a station is highly site-specific. The goal is to make
287 the station as easy to access as possible and close to nearby origins and destinations as possible
288 (Wright and Hook, 2007). Another criteria for the stop is waiting time, which is influenced by the
289 headway in the design of the BRT system. Waiting time is an important factor that determines the
290 overall quality of BRT. In developed countries, the ideal waiting time for buses is 5 – 10 minutes,
291 with a maximum tolerance in the range of 10 – 20 minutes (Meakin, 2004). In some literature
292 regarding the evaluation of BRT shelter locations, land price or land value is one of the indicators.
293 For example, Transmilenio Bogota, with a walking distance of > 5 minutes from the BRT stop,
294 can reduce land values (Rodriguez and Targa, 2004).

295 Mix-used entropy index is a method that quantifies the land-use model, which is that the
296 more mixed types of land-use in one area can improve active transport viability (Handy, 2005) as
297 cited in (Gehrke and Clifton, 2019). Mix-used entropy has a close relationship with accessibility,
298 which is an interaction that occurs between the components of land-use and transportation. An
299 area where the mix-use entropy index is high logically will also have a high accessibility value.
300 Mix-use entropy index calculated using Equation (4).

301

$$302 \quad EI = \frac{-\sum_{k=0}^n (A_{ij} \ln A_{ij})}{\ln N} \quad (4)$$

303

304 Where Ei is the mix-used entropy index, A_{ij} is a comparison between land-use area i and
305 total land-use area (j). N is the number of types of land-use in j . Another reference for accessibility
306 criteria that is quite detailed in setting the position of the stop is The BRT Standard issued by ITDP.
307 The minimum location of the bus stop is 26 m and ideally 40 m from the intersection. The distance
308 between stops is not too far between 300 m to 800 m, with the most optimal distance between
309 stops being 450 m (ITDP, 2016). We try to incorporate these site-specific criteria from the BRT
310 standard, as it distance-based measurement and has a development impact on planning the new
311 location of BRT stops.

312 Some references in utility-based criteria (Hsiao et al., 1997) analyze transit pedestrian
313 accessibility using GIS and highlight a strong relationship between transit service ridership and
314 walking access to transit services. Another reference is (Gan et al., 2005) proposed a system
315 accessibility model using the Florida Transit Geographic Information System (FTGIS).
316 Accessibility in this model is defined by the number of people served in the transit catchment area,
317 a three-quarter mile buffer zone around the transit stops. A composite measurement method of

318 accessibility conducted by (Irmawandari and KDME Handayeni, 2019) using a walk and ride
 319 accessibility index on a rail-based local train in Surabaya, Indonesia, resulted in a high positive
 320 correlation of 0.99 between the number of passengers and accessibility index. These previous
 321 studies concluded that the number of passengers in utility-based measurement is the closest
 322 indicator to capturing transit accessibility. Another reason is that the output of the regression model
 323 can easily understand if the number of passengers becomes the dependent variable. This study
 324 aims to plan a new transit system that we hope can maximize the users of the transit system. Based
 325 on the literature review and previous studies related to the accessibility criteria for the location of
 326 the BRT stop, several variables synthesized can be seen in Table 1.

327
 328 Table 1
 329 Synthesized Variables
 330

Literature	Variables	Measurement	Symbol
(Hsiao et al., 1997), (Gan et al., 2005), (Irmawandari and KDME Handayeni, 2019)	Number of passenger (people)	Utility-based	Y
(Polzin et al., 2002), (Meakin, 2004), (Stewart, 2014)	Waiting time (minutes)	Utility-based	X ₁
(ITDP, 2016)	Distance of stops to the road intersection (m)	Distance-based	X ₂
(ITDP, 2016)	Distance between stops (m)	Distance-based	X ₃
(Handy, 2005), (Gehrke and Clifton, 2019)	Mix-used entropy index (index)	Utility-based	X ₄
(Rodriguez and Targa, 2004), (Stewart, 2014), (Foda and Osman, 2010, 2008), (Malekzadeh and Chung, 2019)	Travel time by walking to stops/first mile (minutes)	Distance-based	X ₅
(Malekzadeh and Chung, 2019)	Total travel distance/origin to destination (km)	Distance-based	X ₆
(Polzin et al., 2002), (Zhao et al., 2003), (Gan et al., 2005), (Malekzadeh and Chung, 2019)	Population density (people/km ²)	Utility-based	X ₇
(Rodriguez and Targa, 2004), (Stewart, 2014), (Malekzadeh and Chung, 2019)	Travel cost (IDR)	Utility-based	X ₈
(Wright and Hook, 2007), (ITDP, 2016)	Potential trip generation/ADT (vehicle/day)	Utility-based	X ₉
(Rodriguez and Targa, 2004), (Yang et al., 2020), (Zhang et al., 2020)	Land value (IDR/m ²)	Distance-based	X ₁₀

331
 332 **3. Research Methodology and Data**

333
 334 **3.1. On-board survey**

335
 336 The daily passenger data of BRT in the study area is not officially available. The BRT
 337 system is at an early stage and still uses manual ticketing as this research was conducted. The on-
 338 board survey was performed to calculate the number of daily passengers at each BRT stop, as the
 339 data are needed for dependent variables in this study. The survey took the bus from the initial stop
 340 to the last stop in the study area and recorded the number of passengers on the bus, descending
 341 passengers, and boarding passengers.

342 There are two round-trip BRT routes in the study area, with each stop having four arrivals
 343 scheduled daily. The number of passengers used for analysis is the total of boarding and alighting
 344 passengers at each stop. The survey begins within the first schedule at the initial Nol-kilometer
 345 BRT stop. As scheduled, the bus will arrive at 7:30 a.m. After passing within four bus stops, the
 346 first route ends at Km.6 bus stop. In the last stops of the first route, the surveyor transit to go back
 347 to Nol-kilometer and wait until the first bus arrived at the second route. After passing six bus stops,

348 the second route ends at the Nol-kilometer stop. The survey continued on the following bus
 349 schedule until the last schedule, estimated at 4:00 p.m. However, there is no reliable bus schedule
 350 at each stop. The officially published schedule is just the first and last departing time at the initial
 351 bus stop. The on-board survey is the initial data collection used to find the number of passengers
 352 variables. The route of the on-board survey can be seen in Figure 2.
 353

354
 355

356 Fig. 2. On-board survey route
 357

358 3.2. Questionnaire 359

360 Questionnaires were distributed to passengers during the on-board survey on the bus.
 361 However, it is quite difficult for passengers to fill out questionnaire forms during the trip,
 362 especially for passengers with short distances. So we do more direct interviews and help fill out
 363 the questionnaire form. We ensure the bus passengers get the questionnaires before descending
 364 and after boarding. Thus, the number of passengers within the on-board survey is the same as the
 365 number of respondents. This method is possible because the number of passengers is relatively
 366 small and the headway of the bus is very long (> 2 hours) so that when the bus arrives, all the
 367 passengers at the stop will get on the bus (the stop has become empty). Data from the questionnaire
 368 included passenger gender, job, age range, and travel purpose with anonymous identity for an
 369 overview. However, the essence of the questionnaire question is to answer the variable conditions.

370 The questionnaire is used to find the waiting time (X_1), the passenger's origin point before
 371 boarding to BRT stop, and the destination (O-D). Another question is the mode that passengers
 372 used to BRT stop (first-mile) and leaving BRT stop (last-mile) and their travel cost (X_8). However,
 373 because the BRT cost is flat, we notice the key difference in cost is at their first-mile and last-mile.
 374 The origin and destination (O-D) point of passengers can be converted into a spatial database that
 375 is used to draw other variables like travel time (X_5) and travel distance (X_6) using a network dataset.
 376 Other variables such as the Mix-used entropy index (X_4), Population density (X_7), Land value
 377 (X_{10}), and Potential trip generation (X_9) are compiled using combined O-D and secondary data.
 378

379 3.3. Secondary and crowdsourced data 380

381 Secondary data were previously available data collected from indirect sources. Several
 382 secondary data were obtained in this study, including from government agencies such as land-use
 383 data, road classes, and related regulations. In addition to compiling road network datasets and
 384 verifying variables such as travel time, data sourced from passive crowdsourcing was also used in
 385 this study, including OpenStreetMap (OSM). ArcGIS Editor for OpenStreetMap is an ArcMap
 386 tool that supports using OpenStreetMap data inside ArcGIS. The tools can load .osm files, apply
 387 symbology, contribute data back to OSM, and create a network dataset from OSM data.

388 From a network dataset, variables such as distance of stops to the road intersection (X_2) and
 389 distance between stops (X_3) can be drawn. The O-D data of passengers can be converted into a
 390 point using geolocation services such as Google Maps API and validated data variables from
 391 questionnaires such as travel time (X_5) and travel distance (X_6). Another variable validated from a

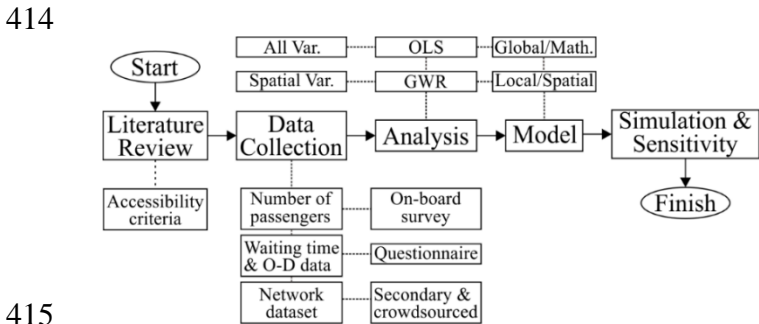

392 network dataset is travel cost (X_8) by assumed distance and mode used. An overlay of a network
 393 dataset with land-use characteristics such as land value, potential trip generation, and the mix-used
 394 entropy index can give robust data.

395
 396 **3.4. Data preparation**

397
 398 This paper uses OLS to get significance criteria and perform the classical assumption test
 399 to obtain a significant mathematical model. The significant model for OLS is determined using
 400 best subset regression by comparing adjusted R^2 and Cp-Mallows values.

401 Classical assumption tests were conducted on the model, such as the heteroscedasticity test,
 402 autocorrelation test, multicollinearity test, and the normal distributed test for residuals. The global
 403 model result possibly contains non-spatial variables. The non-spatial variables were variables that
 404 do not have geolocation information in their data and can not include in spatial analysis, such as
 405 GWR. As for getting the spatial analysis unit, the study area within the administrative boundaries
 406 was divided into a grid of 100 m x 100 m. The grid division resulted in 10246 units with a total
 407 area of $10246 \times (100 \text{ m} \times 100 \text{ m}) = 102.46 \text{ km}^2$. The OLS performed again on spatial variables and
 408 the classical assumption test to get a global regression model.

409 The simulation of the GWR model in the study area was performed by considering the
 410 parameters in the GWR output, such as the condition value, standard error, local R^2 , and the
 411 resulting predicted Y value. Furthermore, the sensitivity test was conducted by configuring
 412 variables spatially to see changes in the model, especially variables directly related to the operation
 413 of the BRT. The flowchart of this research methodology can be seen in Figure 3.

415
 416
 417 Fig. 3. Research flowchart
 418

419 **4. Results and discussion**

420
 421 **4.1. The global regression model**

422
 423 The on-board survey counted boarding and alighting passengers from eight BRT stops,
 424 resulting in total 137 passengers using BRT in a day within the study area. Nol-kilometer stop as
 425 the initial stop located downtown and surrounded by the commercial, office complex, and
 426 recreation land-use has the highest number of passengers. However, the lowest usage is at
 427 Sudimampir stops, although it is located in downtown and commercial area. This phenomenon
 428 slightly shows the influence of criteria that are quite broad and interesting to be analyzed further.
 429 The number of passengers at each stop can be seen in Figure 4.

430

431

Using ArcGIS, a network dataset is built based on downloaded OSM data. As we compared the OSM, local government road data, and satellite imagery, OSM has more detail and reached 1091.86 km total road length compared to 790.13 km of local government data. We check the validity of network attributes such as one-way protocols, speed limit, intersection signal, U-turn restriction, etc. It will impact the calculation of travel distance and time. The O-D data of passengers from the questionnaire were converted into geolocation and plotted into a network dataset. We can see the distribution of passengers for each bus stop and plot the possible route passengers take to go to BRT stops using the combined fastest and shortest route method.

From the geolocation O-D, we can see that the distribution of passengers in the study area can reach far, with the farthest distance being 6 km. However, there is diversity in the mode passengers use to reach or leave BRT stops, as the farthest passengers use a car and motorcycle, and the shortest distance is just by walking. To equalize this, we convert the distance to walking time using a 4.39 km/h standardized walking speed (National Research Council (U.S.). Transportation Research Board., 2000). The plotted O-D data can be seen in Figure 5.

450

451

452 Fig. 5. The passenger's O-D and BRT stop locations.

453

454

455

456

457

The distance-based variables such as distance of stops to the road intersection (X_2) and distance between stops (X_3), and land-use characteristic variables such as Mix-used entropy index (X_4), Population density (X_7), Potential trip generation (X_9), and Land value (X_{10}) can be calculated based on grid unit. Then variables condition at each bus stop and passenger's O-D point

458 can be extracted for OLS analysis. Spatial variables can be calculated based on grid units, as shown
 459 in Figure 6.
 460

461
 462
 463 Fig. 6. Spatial Variables (From left to right: X₂, X₄, X₇, X₉, X₁₀)
 464

465 The results of OLS regression simultaneously on all variables showed that only three
 466 variables rejected the null hypothesis with a p-value > alpha 0.05 out of a total of 10 predictive
 467 variables. In addition, several variables with high Pearson correlation values (> 0.5) also failed to
 468 reject the null hypothesis. Thus, optimizing the model using the best subset regression by
 469 comparing the adjusted R² and Cp-Mallows values on all possible paired variables was necessary.
 470 The model selection results with the best subset regression can be seen in Table 2 (selected models
 471 in bold and italic).

472
 473 Table 2
 474 Best Subset Regression Results
 475

Variables	Adjusted R ²	Cp-Mallows
X ₉	0.383	167.363
X ₉ / X ₁₀	0.632	89.252
X ₆ / X ₉ / X ₁₀	0.848	29.821
X ₁ / X ₆ / X ₉ / X ₁₀	0.869	23.853
X ₂ / X ₃ / X ₇ / X ₈ / X ₁₀	0.919	12.764
X ₁ / X ₂ / X ₃ / X ₆ / X ₇ / X ₁₀	0.942	8.907
<i>X₁ / X₂ / X₃ / X₄ / X₆ / X₇ / X₁₀</i>	<i>0.964</i>	<i>6.018</i>
X ₁ / X ₂ / X ₃ / X ₄ / X ₅ / X ₆ / X ₇ / X ₁₀	0.963	7.449
X ₁ / X ₂ / X ₃ / X ₄ / X ₅ / X ₆ / X ₇ / X ₉ / X ₁₀	0.959	9.150
X ₁ / X ₂ / X ₃ / X ₄ / X ₅ / X ₆ / X ₇ / X ₈ / X ₉ / X ₁₀	0.952	11.000

476
 477 As the rule of best subset, the maximum adjusted R² and the minimum Cp-Mallows value
 478 were selected as the best model. Three variables were eliminated in the selected model as it failed
 479 to reject the null hypothesis (p-value < alpha 0.05). However, the selected variables in the best
 480 subset need to be statistically validated using the classical assumption test. The results of the
 481 assumption test can be seen in Table 3.

482
 483 Table 3
 484 Classical Assumption Test Result
 485

Test	Output	Interpretation
Heteroscedasticity	p-value = 0.231 or > 0.05	Residuals were homoscedastic
Autocorrelation	p-value = 0.523 or > 0.05	No autocorrelation in the residual
Multicollinearity	VIF value < 10	No multicollinearity between independent variables
Normality	p-value = 0.623 or > 0.05	Residuals were normally distributed

486 Based on the OLS and classical assumption test results, the criteria for the accessibility
487 model of BRT stop locations in the study area include waiting time (X_1), the distance of stops to
488 the road intersection (X_2), the distance between stops (X_3), mix-use entropy index (X_4), travel time
489 by walking to stops/first mile (X_6), population density (X_7) and land value (X_{10}). The global
490 regression model can be seen in Equation (5).

$$491 \\ 492 Y = -20.198 + 0.229X_1 - 0.040X_2 + 0.005X_3 + 5.292X_4 - 0.159X_6 + 0.00045187X_7 + 0.00000893X_{10} \quad (5)$$

493
494 As we can see from the mathematical model, the mix-used entropy index (X_4) has the
495 highest coefficient with a positive sign. It can be interpreted that the mix-used entropy index has
496 the most significant influence in describing the number of passengers as it means the BRT stop
497 locations accessibility. The positive sign described its influence direction as linear; if we increased
498 the X_4 value, it would increase accessibility. We can look back to the data, as the location of the
499 Nol-kilometer stop is surrounded by multiple land-use at downtown, with the highest number of
500 passengers. The lowest coefficient is the land value (X_{10}). Although it has a positive sign, we can
501 assume that as the BRT development in the study area is at an earlier stage, it has not yet had a
502 strong impact on land values.

503 The variable with a negative coefficient is the distance of stops to the road intersection (X_2).
504 As we do not expect it, this phenomenon can explain the nature of the utility-based variable. The
505 passengers are more prefer the stop location near the road intersection. Theoretically, the
506 intersection is the nodes of the road network that have more accessibility, although it had a negative
507 impact on BRT's operations. The negative sign for total travel distance/origin to destination (X_6)
508 is reasonable. As far as the travel distance, the accessibility decreased. This result explains that the
509 passenger prefers short-distance travel using BRT.

510 The potential trip generation (X_9) is failed to reject the null hypothesis and not included in
511 the model. As the data are based on the assumption of average daily traffic of land-use
512 characteristics, we do not expect it to be rejected. However, we assumed that the land-use
513 characteristic in the study area has a weak relationship with the traffic generation assumption.

514 515 **4.2. The GWR model**

516
517 The spatial model of BRT stop locations was built using GWR. However, the global
518 model's OLS result includes non-spatial variables that could not be arranged into grid cells, such
519 as the waiting time (X_1) and the distance between stops (X_3). The GWR model was built based on
520 spatial variables, including the number of passengers (Y), the distance of stops to the road
521 intersection (X_2), mix-use entropy index (X_4), population density (X_7), potential trip generation
522 (X_9) and land value (X_{10}). The OLS was performed on the spatial variables to get the global model.
523 The output was relatively similar to non-spatial included OLS, where the X_9 variable failed to
524 reject the null hypothesis. However, the global model significance or adjusted R^2 decreased to
525 0.861 from 0.964 because of the missing non-spatial explanatory variables. The global model of
526 spatial variables can be seen in Equation (6).

$$527 \\ 528 Y = -9.688 - 0.016X_2 + 27.088X_4 + 0.00028X_7 + 0.0000048X_{10} \quad (6)$$

529
530 Before GWR was performed, the spatial autocorrelation (Global Moran's I) was conducted
531 to see each variable's spatial dependency. Using ArcGIS, the test results showed the index value

532 of each of these variables > 0.05 , $p\text{-value} < 0.01$. The critical value (z-score) of each variable was
 533 greater than 2.58. There is less than a one percent likelihood that the clustered pattern results from
 534 random chance, which indicates a spatial dependency for all variables. Tobler's first law of
 535 geography can interpret these results, "Everything is related to everything else, but near things are
 536 more related than distant things."

537 GWR analysis was performed using ArcGIS and considering the parameters in the GWR
 538 output, such as the condition value, standard error, local R^2 , and the resulting predicted Y value.
 539 There are several kernel approaches and bandwidth optimization in GWR, as we compare fixed
 540 and adaptive kernel and bandwidth optimization with AICc and CV. Based on the global model,
 541 we assumed the adaptive kernel has more advantage in maximizing their model significance by
 542 looking at high variance in data variable and distance location of each BRT stop. However,
 543 comparing the parameter's output is the best approach to selecting the model. The parameters
 544 output of GWR can be seen in Table 4.

545

546 Table 4

547 Parameter of Output GWR

548

Parameter	Fixed AICc	Fixed CV	Adaptive AICc
Bandwidth	2711.97	52.94	-
Residual Squares	11.683	32.56	6.432
Effective Number	6.504	5.005	7.107
Sigma	2.795	3.297	2.684
AICc	-7,631,30	130.2	-133.70
R^2	0.978	0.939	0.988
R^2 Adjusted	0.897	0.857	0.905

549

550 The bandwidth used in Fixed AICc is 2711.97 m and based on the distance of each BRT
 551 stop location, it can reach the location of the neighboring BRT stop. However, in Fixed CV the
 552 bandwidth distance is relatively small at 52.94 m, and it could not reach the neighboring location.
 553 The adaptive AICc has no bandwidth output information as the bandwidth value is adjusted in
 554 every stop location until it reaches its neighbor. Based on the adjusted R^2 value, the AICc
 555 bandwidth optimization has better significance, and as the AICc finds the optimum AIC value, it
 556 has the smallest AICc output over CV. The adaptive kernel resulted in the highest adjusted R^2 ,
 557 although Fixed AICc has the smallest AICc output. The chosen model is the adaptive AICc as it
 558 has more advantages of simulation in the study area with an adjusted bandwidth value. The chosen
 559 GWR model can be compared with a global model of the spatial variable before, resulting in GWR
 560 having a significant value that can be seen in Table 5.

561

562 Table 5

563 Significance of global model and GWR model

564

Parameter	OLS Regression (Best subset)	GWR (Adaptive AICc)
R^2	0.940	0.988
Adjusted R^2	0.861	0.905
AIC	21.017	-133.700

565

566 Based on key output parameters, the GWR has a higher adjusted R^2 and smallest AIC. This
 567 result explains that the accessibility model of BRT stop locations has spatial influence that can be
 568 better explained in GWR than in the global model. Furthermore, GWR produced a local regression

569 model at each BRT stop location with different values that consider each location's variable
 570 conditions, as seen in Table 6.

571

572 Table 6

573 A local model of GWR

574

BRT Stop Locations	Local Model of GWR
Nol-Kilometer	$Y = -10.189 - 0.024 X_2 + 19.531 X_4 + 0.0007 X_7 + 0.000002 X_{10}$
RS-Ulin	$Y = -9.607 - 0.024 X_2 + 18.533 X_4 + 0.0007 X_7 + 0.000002 X_{10}$
Golden-Tulip	$Y = -9.487 - 0.024 X_2 + 18.344 X_4 + 0.0007 X_7 + 0.000002 X_{10}$
Sudimampir	$Y = -9.947 - 0.024 X_2 + 19.038 X_4 + 0.0007 X_7 + 0.000002 X_{10}$
Polresta	$Y = -5.94 - 0.021 X_2 + 14.882 X_4 + 0.0007 X_7 + 0.000001 X_{10}$
Jasa-Raharja	$Y = -4.346 - 0.02 X_2 + 16.039 X_4 + 0.0003 X_7 + 0.000005 X_{10}$
KFC-A.Yani	$Y = -4.458 - 0.02 X_2 + 16.129 X_4 + 0.0003 X_7 + 0.000005 X_{10}$
Km.6	$Y = -3.676 - 0.021 X_2 + 13.636 X_4 + 0.0003 X_7 + 0.000006 X_{10}$

575

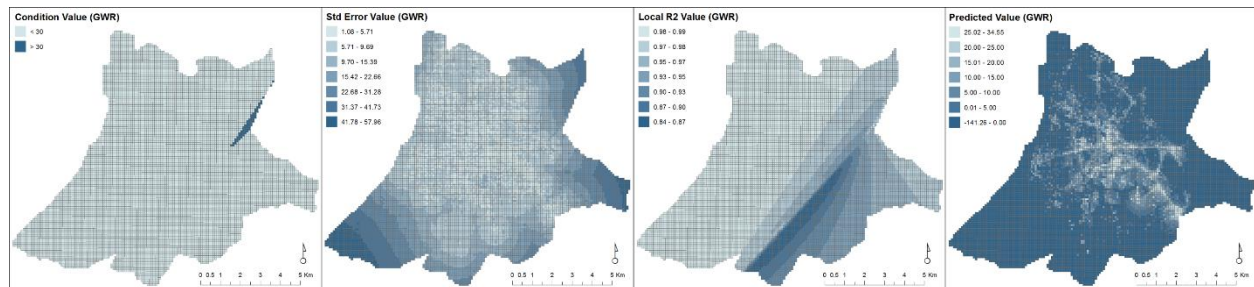

576 **4.3. Model simulation and sensitivity**

577

578 The advantage of the GWR model is that it can be simulated through the study area and
 579 results in a visual-spatial model rather than only a mathematical model. The visual-spatial model
 580 can be better understood, and the location information is helpful in decision making, planning, and
 581 development of the new BRT corridor. Simulation performed using ArcGIS and chosen GWR
 582 model with adaptive kernel and AICc Bandwidth optimization.

583 The simulation output has a parameter to consider. The output has 66 grid cells with
 584 condition values > 30. As a rule of thumb of GWR simulation, do not trust results for features with
 585 a condition number larger than 30, equal to Null or for shapefiles, equal to -
 586 1.7976931348623158e+308 (<https://desktop.arcgis.com>). We eliminate that 66 grid cells from the
 587 output simulation. The standard error value tended to be greater in urban-periphery areas, as the
 588 location of BRT stops only in the downtown area. The model has low adaptation to variable
 589 conditions in urban-periphery areas. The local R² value was in the range 0.84 – 0.99, where this
 590 value was above the average and significant (> 0.5). There was a predicted value in the negative
 591 range (-), so adjustments were made by eliminating the cells as the negative predicted value mean
 592 predicted number of passengers (Y). We considered that area had no accessibility value for BRT
 593 stop locations. The GWR simulation parameter output can be seen in Figure 7.

594

595

596

597 Fig. 7. Simulation Output (from left to right: condition, std. Error, Local R², and pred. value)

598

599 For more informative results, the level of accessibility measured by the number of
 600 passengers or predicted Y could be classified into five classes: very low, low, moderate, high, and

601 very high. The classification was calculated using a natural breaks (Jenks) approach, as shown in
602 Figure 8.
603

604
605
606 Fig. 8. Accessibility Level of BRT Stop Locations
607

608 From the model, we can see the BRT stop location with very high accessibility widespread
609 on the arterial road of the study area. We can divide an area with very high accessibility into two
610 clusters for corridor development. First is an area with a high potential for corridor development
611 but lacks the main infrastructure such as pedestrian connectivity. The eastern part Sungai-Lulut is
612 a suburban area growing rapidly due to low-priced housing development. On the main road
613 corridor, there is also a supporting commercial area. However, as land-use grows rapidly, the
614 development of transportation is inadequate. Where almost every peak hour, there is congestion
615 due to private vehicles. The western part has potential through the HKS road corridor. An
616 alternate is through the Teluk-Dalam road corridor as it is connected with the port of Trisakti.
617 However, the western corridor had a natural barrier development of the Barito River. The southern
618 part has potential through a new ring road corridor, Basirih, and connected to Gubernur Soebardjo
619 Ring-road. However, the ring road connection is still developing and has limited service.

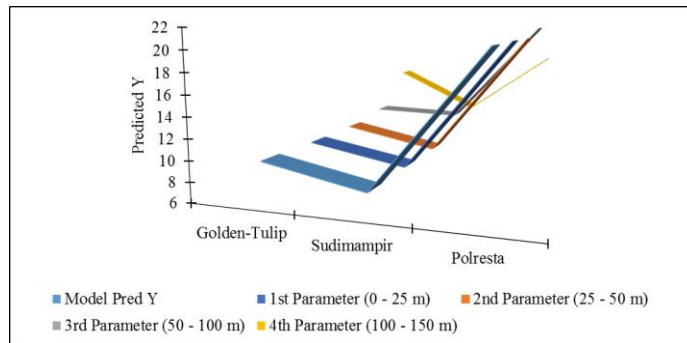

620 The second cluster is an area with a high potential for corridor development and has the
621 main infrastructure such as pedestrian connectivity. The area in this cluster is the northern part
622 through the Kayu-Tangi road corridor or Brigjen H.Basri road and the central area through the
623 Gatot-Subroto road corridor. The northern area had high potential passengers from schools,
624 universities, and office-complex and the Gatot-Subroto road corridor is a high-density commercial
625 corridor.

626 The sensitivity test of the model was performed by gradually intervening on variables. In
627 this case, the distance of stops to the road intersection (X_2) was chosen as it is directly related to
628 BRT operations and is most realistic for spatial intervention. The simulation is performed by
629 gradually increasing the distance of the BRT stop location from the road intersection. Based on
630 the BRT standard, the minimum distance was 26 m, and the ideal was 40 m from the intersection.
631 We choose three BRT stops: Golden-tulip, Sudimampir, and Polresta, as their existing location is
632 below 26 m from the intersection. The sensitivity test parameters are in Table 7.
633

634 Table 7
 635 Sensitivity Test Parameters
 636

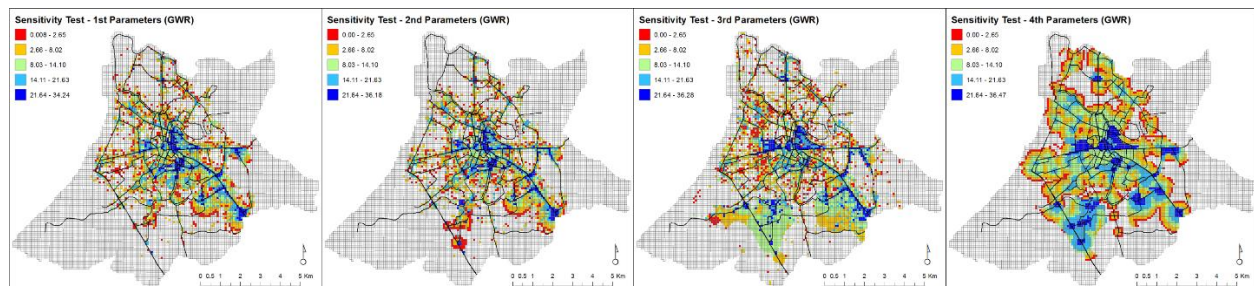

Parameter test	Distance of X_2 (m)	Grid Cell
1 st parameter	0 - 25 m	No shift
2 nd parameter	25 - 50 m	No shift
3 rd parameter	50 - 100 m	Shift by 1 cell
4 th parameter	100 - 150 m	Shift by 2 cells
n th parameter	+50 m	Shift by n - 2 cells

637
 638 The output of this sensitivity test can be broadly seen in the predicted Y value. There has
 639 not been a significant change in the first and second parameters as the new location is still in the
 640 same grid cells and only the value of X_2 changes. However, in the third parameter, there is an
 641 increase in accessibility at the three stops, but in the fourth parameter, there was a decrease in
 642 value at two BRT stops. The comparison of values at each bus stop can be seen in Figure 9.
 643

644
 645
 646 Fig. 9. Sensitivity test
 647

648 In the model before, the X_2 variable has a negative coefficient value which means it has
 649 the opposite value to accessibility. However, in this sensitivity test, increasing the distance of the
 650 BRT stop with the intersection at specific parameters (50 - 100 m) could increase the value of its
 651 accessibility. Although, the predicted Y value dropped at the last parameter above 100 m. Besides
 652 the changes in mathematical value, we can see the changes in the spatial pattern of each parameter
 653 in Figure 10.
 654

655
 656
 657 Fig. 10. Sensitivity Test Spatial Pattern (from left to right: Parameters 1, 2, 3, and 4)
 658

659 As discussed in the mathematical model before, there was no significant change in the first
660 and second parameters. However, in the GWR spatial pattern, we can see changes in the southern
661 area, specifically in the intersections of the south ring road, one of which was caused by the
662 increasing value of the criteria range for the X_2 variable. It can be concluded that the areas with
663 the main intersection are become overestimated in the model.

664 In the third parameter model of the sensitivity test, there was a widespread area in the
665 intersection node of the main roads even though the value was in relatively low classes. However,
666 the periphery of the southern area was drastically becoming an area with vast potential for BRT
667 accessibility. This phenomenon can explain the urban growth of the study area represented by the
668 variable of this research has a potential development direction to the southern area. The southern
669 area had fewer natural barriers, such as large rivers like the Alalak River in the north, the Martapura
670 River in the east, and the Barito River in the west. The existence of a ring road (Gubernur
671 Soebardjo road) and the railroad development plan in the southern area are other supporting facts
672 that the southern area had the highest potential.

673 Furthermore, this result can be a consideration for developing the city and its transit system
674 in the study area. Meanwhile, in the fourth parameter, the widespread area becomes unnatural, as
675 the accessibility is only based on the distance radius of the road intersection. The high range of X_2
676 variables leads to underestimating other variables in the model.

677 5. Conclusions

680 From the results, it can be concluded the spatial criteria which affected the accessibility of
681 BRT stop locations in the study area were the distance of stops to the road intersection (X_2), mix-
682 used entropy index (X_4), population density (X_7), and land value (X_{10}). The global regression
683 model using OLS resulted in 0.861 of R^2 . The spatial autocorrelation (Global Moran's I) test reports
684 spatial dependency on all spatial variables. Using the adaptive kernel and AICc bandwidth
685 optimization, the GWR model resulted in a higher significance R^2 value of 0.905. Furthermore,
686 the AIC of GWR has a smaller value of -133.700 than 21.017 in the OLS model. The results can
687 be evidence of strong consideration that the GWR is better in modeling accessibility of BRT stop
688 location in the study area with spatial dependency in its criteria. We found that the most influential
689 criteria from the model are the mix-used entropy index (X_4). GWR simulation produces a visual-
690 spatial model and shows that the new BRT corridor development in the study area can be divided
691 into two clusters.

692 The concept of accessibility itself continues to evolve and produce new measurement and
693 modeling methods. In this paper, we found that the complexity in composite accessibility
694 measurement can be solved by the regression equation of GWR with easy-to-understand output.
695 The model can incorporate both the objective view of urban variables and the subjective view of
696 passengers. Furthermore, instead of just measuring and modeling the existing accessibility of
697 transit systems, GWR had an advantage in simulation to forecast optimized future transit systems.

698 The method and output in this paper can help the early-stage development of transit
699 systems, specifically the BRT system. Although the BRT system is the easiest to implement, it
700 also has many failure factors that make it abandoned by passengers. BRT's nature that uses existing
701 infrastructure requires a solid study of accessibility in determining new corridors. The accessible
702 and effective transit corridor will reduce the usage of private transportation. Hence, this study can
703 become an alternative reference to help policymakers plan sustainable transportation.

704 However, this paper still needs a lot of improvement. The independent variables crucial to
705 the results can be improved using time-series data, especially if the BRT ticketing has used an
706 electronic system to automatically count the number of passengers at each stop. Furthermore, the
707 non-spatial variable can transform into the spatial variable if sufficient geolocation data are
708 included in the GWR model.

709

710 **Conflict of Interest**

711

712 All the authors have no conflict of interest with the funding entity and any organization
713 mentioned in this article in the past three years that may have influenced the conduct of this
714 research and the findings.

715

716 **Acknowledgments and Declarations**

717

718 This research did not receive any specific grant from funding agencies in the public,
719 commercial, or not-for-profit sectors. The authors are profoundly thankful to the study program
720 coordinator, the thesis examiner team, lecturers, and academic staff of master of civil engineering
721 program, Lambung Mangkurat University, Banjarmasin for their help and support in completing
722 this research. The authors declare that the contents of this article have not been published
723 previously. All the authors have contributed to the work described, read, and approved the contents
724 for publication in this journal.

Conflict of Interest

All the authors have no conflict of interest with the funding entity and any organization mentioned in this article in the past three years that may have influenced the conduct of this research and the findings.

Acknowledgments and Declarations

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors. The authors are profoundly thankful to the study program coordinator, the thesis examiner team, lecturers and academic staff of master of civil engineering program, Lambung Mangkurat University, Banjarmasin for their help and support in completing this research. The authors declare that the contents of this article has not been published previously. All the authors have contributed to the work described, read and approved the contents for publication in this journal.

We have no conflicts of interest to disclose.

Sincerely,

Hendri Yani Saputra
